

# **Fluid and Electrolyte balance**

Anil Gattani

## Body as an open system

Body exchanges materials and energy with its surroundings

# Water

## General

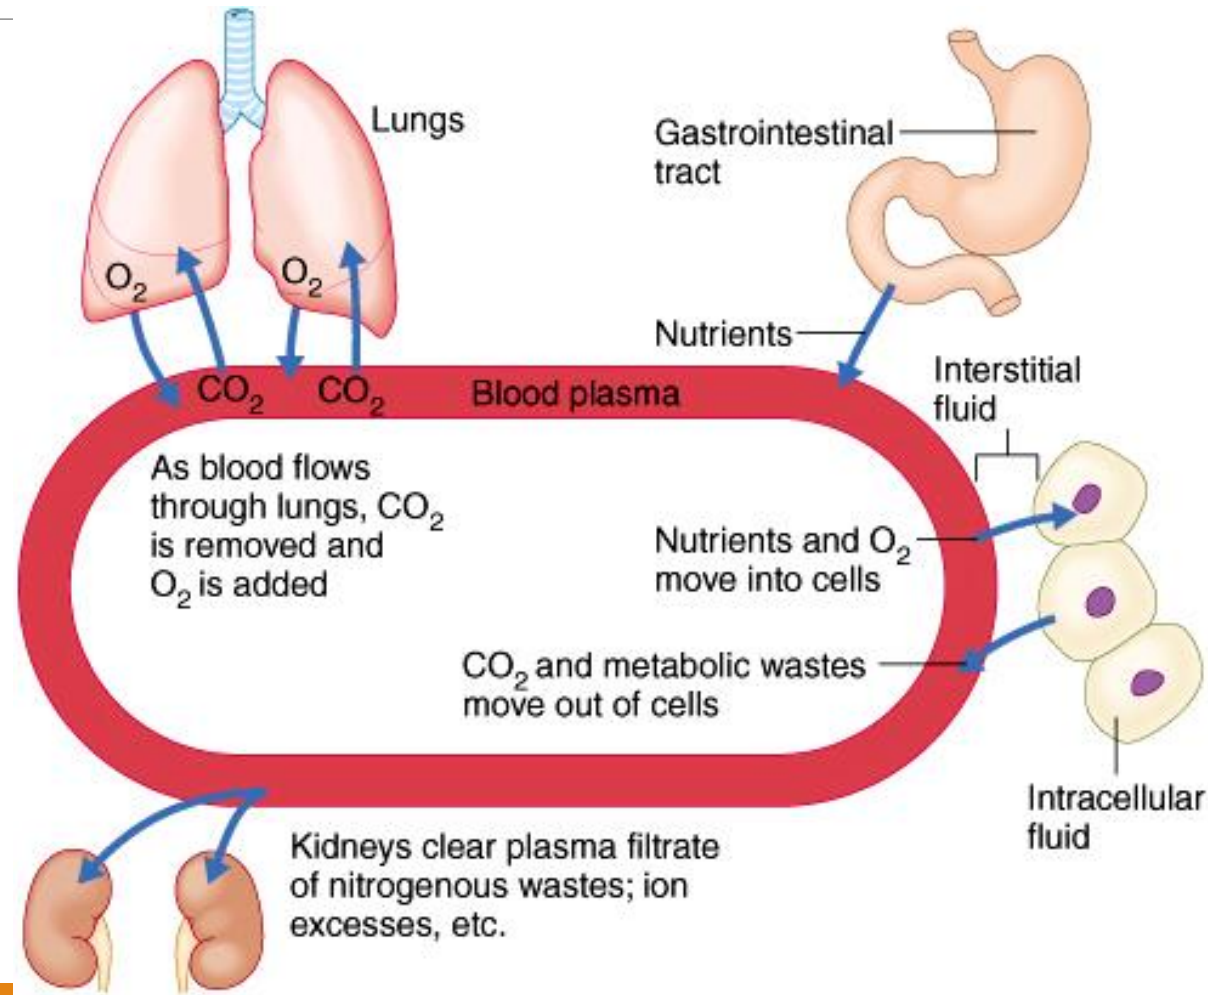

---

- Largest single chemical component of the body: 45-75% of body mass
- Fat (adipose tissue) is essentially water free, so there is relatively more or less water in the body depending on % fat composition
- Water is the solvent for most biological molecules within the body
- Water also participates in a variety of biochemical reactions, both anabolic and catabolic

# Fluid Balance

## Fluid balance

- When in balance, adequate water is present and is distributed among the various compartments according to the body's needs
- Many things are freely exchanged between fluid compartments, especially water
- Fluid movements by:
  - bulk flow (i.e., blood & lymph circulation)
  - diffusion & osmosis – in most regions

Route	Range (l/day)	Regulatory influences
<b>Insensible - lungs</b>	<b>0.3-0.4</b>	<b>Atmospheric vapor pressure (temperature)</b>
<b>Insensible - skin</b>	<b>0.35-0.4</b>	<b>10x increase in burn victims</b>
<b>Sweat</b>	<b>0.1-2 (per hour)</b>	<b>Temperature, exercise</b>
<b>Feces</b>	<b>0.1-0.2</b>	<b>Diarrheal disease</b>
<b>Urine</b>	<b>0.5-1.4-20</b>	<b>Body fluid composition</b>

# FACTORS AFFECTING

## Total Body H<sub>2</sub>O

---

varies depending on body fat:

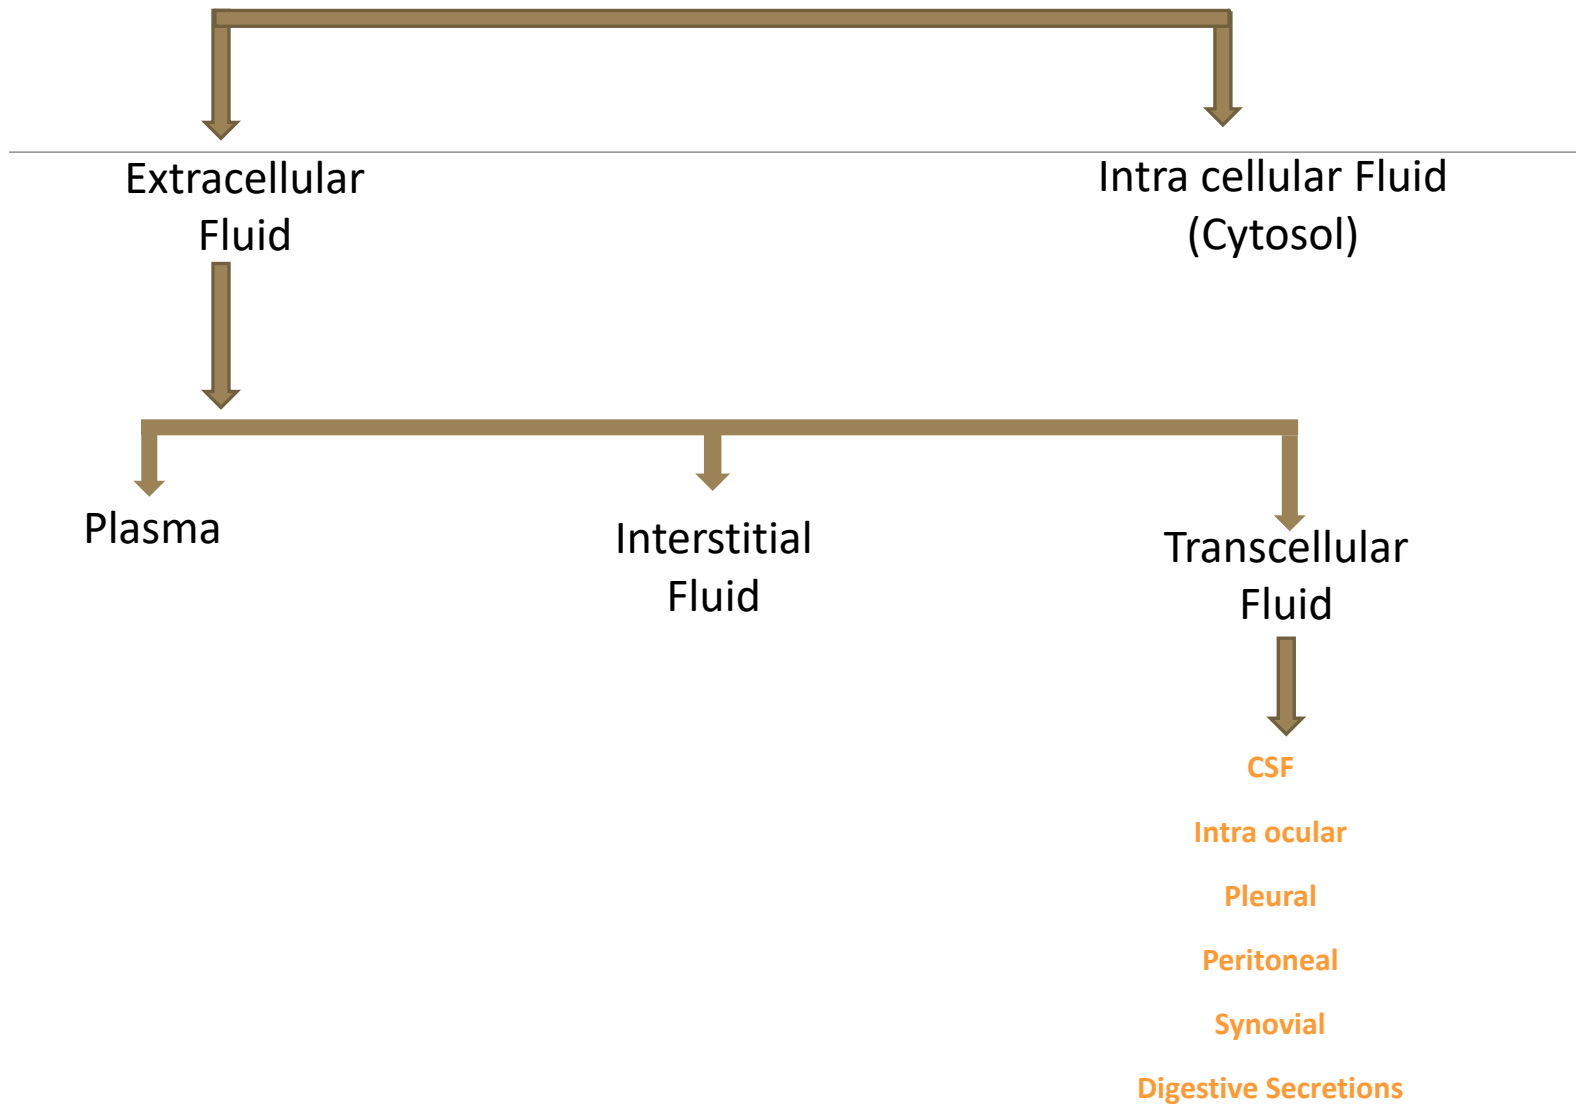

1. Infant: 73-80%
2. Male adult: 60%
3. Female adult: 40-50%
4. Effects of obesity
5. Old age 45%
6. Climate Level of physical activity

# PERCENTAGE OF H<sub>2</sub>O IN TISSUES

# FLUID COMPARTMENTS

# PERCENTAGE OF WATER IN TISSUES

Average 70 kg person total body weight

**42 litres** total H<sub>2</sub>O 60%

**28 l.** Intracellular fluid (ICF) 40% (2/3)

**14 l.** Extracellular fluid (ECF) 20% (1/3)

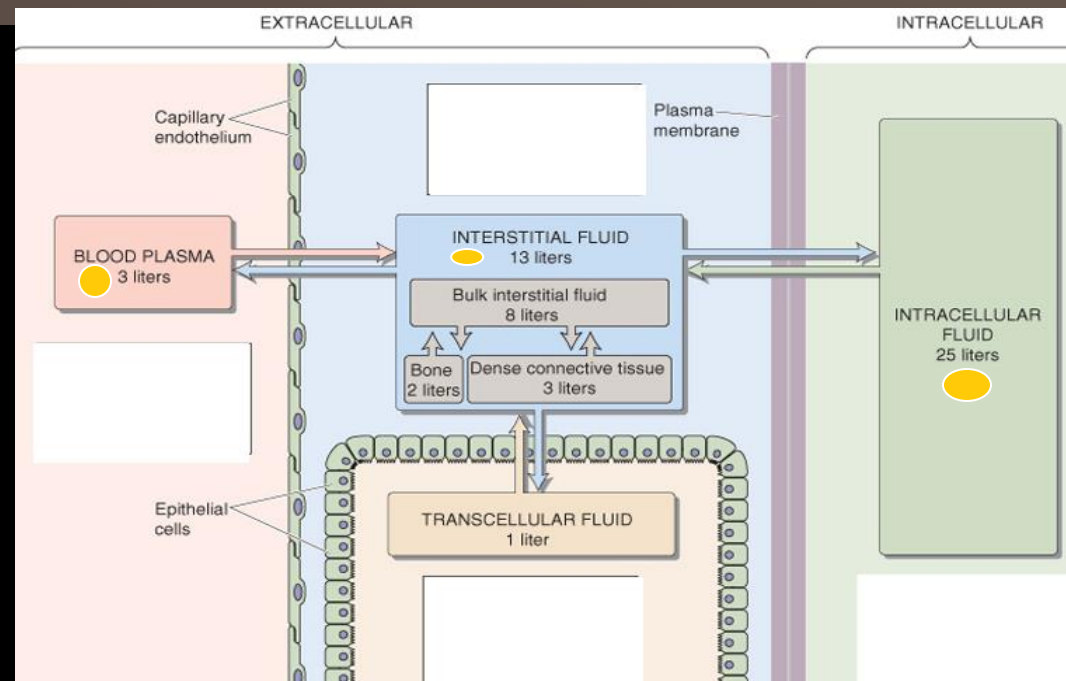

**% is important in fluid therapy**

divided into  $\frac{3}{4}$  ISF and  $\frac{1}{4}$  plasma water

10.5 l. Interstitial fluid (ISF) 15%

3.5 l. Plasma water 5%

TISSUE	% WATER	% BODY Wt.	L of H <sub>2</sub> O
Skin	72	18	9.1
Muscle	76	41.7	22.1
Skeleton	22	16	2.5
Brain	74.8	2.0	1.0
Liver	68.3	2.3	1.0
Blood	83.0	8.0	4.65
Intestine	74.5	1.8	1.0
Adipose Tissue	10.0	10+	0.7

# Regulation of H<sub>2</sub>O Intake

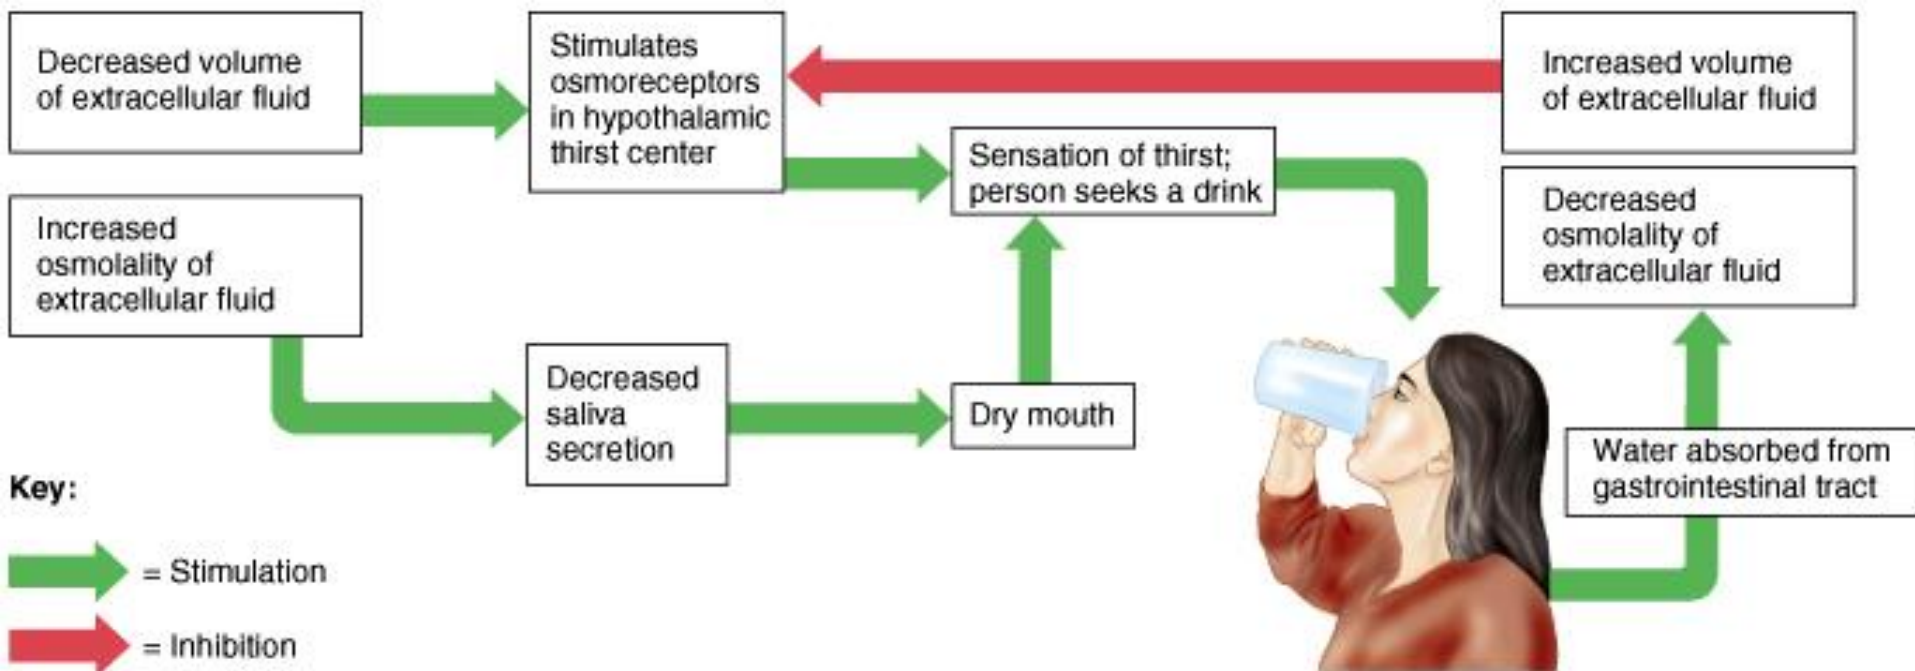

---

The hypothalamic thirst center is stimulated:

1. By a decline in plasma volume of 10%–15%
2. By increases in plasma osmolality of 1–2%
3. Via baroreceptor input, angiotensin II, and other stimuli

# Regulating Fluid Intake - Thirst

Recall the role of the Renin-Angiotensin System in regulating thirst along with the Autonomic NS reflexes diagramed below

# Regulating Fluid Intake - Thirst Quenching

---

Wetting the oral mucosa (temporary)

Stretching of the stomach

Decreased blood/body fluid **osmolarity** = increased hydration (dilution) of the blood is the most important

# Regulation of Fluid Output

---

## Hormonal control

- AntiDiuretic Hormone (ADH) [neurohypophysis]
- Aldosterone [adrenal cortex]
- Atrial Natriuretic Peptide (ANP) [heart atrial walls]

## Physiologic fluid imbalances

- Dehydration: ↓ blood pressure, ↓ GFR
- Overhydration: ↑ blood pressure, ↑ GFR
- Hyperventilation - water loss through lungs
- Vomiting & Diarrhea - excessive water loss
- Fever - heavy perspiration
- Burns - initial fluid loss; may persist in severe burns
- Hemorrhage – if blood loss is severe

# Concentrations of Solutes

---

## Non-electrolytes

- molecules formed by only covalent bonds
- do not form charged ions in solution

## Electrolytes

- Molecules formed with some ionic bonds;
- Disassociate into cations (+) & anions (-) in solutions (acids, bases, salts)
- 4 important physiological functions in the body
  - essential minerals in certain biochemical reactions
  - control osmosis = control the movement of water between compartments
  - maintain acid-base balance
  - conduct electrical currents (depolarization events)

# Distribution of H<sub>2</sub>O & Electrolytes

Recall Starling's Law of the Capillaries which explains fluid and solute movements

## Key to pressure values:

HP<sub>c</sub> at arterial end = 35 mm Hg

HP<sub>c</sub> at venous end = 17 mm Hg

HP<sub>if</sub> = 0 mm Hg

OP<sub>c</sub> = 26 mm Hg

OP<sub>if</sub> = 1 mm Hg

# Distribution of Electrolytes

## Key to fluids:

- = Blood plasma
- = Interstitial fluid
- = Intracellular fluid

## Key to symbols:

- $\text{Na}^+$  = Sodium
- $\text{K}^+$  = Potassium
- $\text{Ca}^{2+}$  = Calcium
- $\text{Mg}^{2+}$  = Magnesium
- $\text{HCO}_3^-$  = Bicarbonate
- $\text{Cl}^-$  = Chloride
- $\text{HPO}_4^{2-}$  = Phosphate
- $\text{SO}_4^{2-}$  = Sulfate

## APPROXIMATE IONIC COMPOSITION OF THE BODY H<sub>2</sub>O COMPARTMENTS

	Plasma, mmoles/L	Interstitial fluid, mmoles/L	Skeletal muscle cell, mmoles/L
Ion			
<b>Cations</b>			
Na <sup>+</sup>	142.0	145.1	10.0
K <sup>+</sup>	4.3	4.4	140.0
Ca <sup>2+</sup> (ionized)	2.5	2.4	1.0
Mg <sup>2+</sup> (ionized)	1.1	1.1	17
Others	4.0		
<b>Total</b>	<b>154</b>	<b>153</b>	<b>168</b>
<b>Anions</b>			
Cl <sup>-</sup>	114.0	117.4	4.0
HCO <sub>3</sub> <sup>-</sup>	24.0	27.1	7.0
HPO <sub>4</sub> <sup>2-</sup> , H <sub>2</sub> PO <sub>4</sub> <sup>-</sup>	1.0	1.2	40.0
Proteins	1.5	0.1	3.0
Other	10.0	6.2	84.0
<b>Total</b>	<b>154</b>	<b>153</b>	<b>138</b>

# Distribution of Major Electrolytes

---

$\text{Na}^+$  and  $\text{Cl}^-$  predominate in extracellular fluids (interstitial fluid and plasma) but are very low in the intracellular fluid (cytoplasm)

$\text{K}^+$  and  $\text{HPO}_4^{2-}$  predominate in intracellular fluid (cytoplasm) but are in very low concentration in the extracellular fluids (interstitial fluid and plasma)

At body fluid pH, proteins  $[\text{P}^-]$  act as anions; total protein concentration  $[\text{P}^-]$  is relatively high, the second most important “anion,” in the cytoplasm,  $[\text{P}^-]$  is intermediate in blood plasma, but  $[\text{P}^-]$  is very low in the interstitial fluid

# Distribution of Minor Electrolytes

---

$\text{HCO}_3^-$  is in intermediate concentrations in all fluids, a bit lower in the intracellular fluid (cytoplasm); it is an important pH buffer in the extracellular compartments

$\text{Ca}^{++}$  is in low concentration in all fluid compartments, but it must be tightly regulated, as small shifts in  $\text{Ca}^{++}$  concentration in any compartment have serious effects

$\text{Mg}^{++}$  is in low concentration in all fluid compartments, but  $\text{Mg}^{++}$  is a bit higher in the intracellular fluid (cytoplasm), where it is a component of many cellular enzymes

# Electrolyte Balance

---

Aldosterone  $\uparrow$   $[\text{Na}^+]$   $[\text{Cl}^-]$   $[\text{H}_2\text{O}]$   $\downarrow$   $[\text{K}^+]$

Atrial Natriuretic Peptide (opposite effect)

Antidiuretic Hormone  $\uparrow$   $[\text{H}_2\text{O}]$  ( $\downarrow$  [solutes])

Parathyroid Hormone  $\uparrow$   $[\text{Ca}^{++}]$   $\downarrow$   $[\text{HPO}_4^-]$

Calcitonin (opposite effect)

Female sex hormones  $\uparrow$   $[\text{H}_2\text{O}]$

# Plasma Osmolarity Measures ECF Osmolarity

Plasma is clinically accessible

Dominated by  $[\text{Na}^+]$  and the associated anions

Under normal conditions, ECF osmolarity can be roughly estimated as:

$$P_{\text{OSM}} = 2 [\text{Na}^+]_p \quad 270\text{-}290 \text{ mOSM}$$

# Disorders of H<sub>2</sub>O Balance: Dehydration

① Excessive loss of H<sub>2</sub>O from ECF

② ECF osmotic pressure rises

③ Cells lose H<sub>2</sub>O to ECF by osmosis; cells shrink

(a) Mechanism of dehydration

# Primary Disturbance

## Water Loss

### ECF OSMOLARITY ?

1. H<sub>2</sub>O moves out of cells
2. ICF Volume decreases  
(Cells shrink)
3. ICF Osmolarity increases
4. Total body osmolarity remains higher than normal

## Over Hydration

### ECF OSMOLARITY ?

1. H<sub>2</sub>O moves into the cells
2. ICF Volume increases  
(Cells swell)
3. ICF Osmolarity decreases
4. Total body osmolarity remains lower than normal
